## CLAIMS

- 1. A filtering device for a narrow-band terminal in a private installation connected to an access network carrying narrow-band services (analogue or ISDN) and broad-band services (xDSL or HomePNA), characterised in that it comprises low-pass filtering means (F) and isolation means (I) enabling the device to have a high input impedance isolating it from the installation when the narrow-band terminal is in the on-hook state whilst allowing the ringing signal to pass.
- 2. A filtering device according to Claim 1, characterised in that the isolation means comprise Zener diodes in opposite orientations and disposed in series.
- 3. A filtering device according to any one of the preceding claims, characterised in that the isolation means comprise switching diodes in opposite orientations and disposed in parallel.
- 4. A filtering device according to Claim 1, 2 or 3, characterised in that the filtering means include one or more low-pass filters.
- 5. A filtering device according to any one of the preceding claims, characterised in that the filtering means include a filter of the LC type and in that the isolation means are placed at the inputs of the said filter.
- 6. A filtering device according to any one of Claims 1 to 4, characterised in that the filtering

means (F) include a filter of the LC type and in that the isolation means (I) are placed between the inductors and the capacitor of the said filter.

- 7. A filtering device according to any one of the preceding claims, characterised in that the filtering and isolation means are functionally distinct.
- 8. A filtering device according to any one of Claims 1 to 6, characterised in that the filtering and isolation means are functionally interlinked.
- 9. A filtering device according to Claim 8, characterised in that the filtering and isolation means include a low-pass filter, a diode bridge and at least one relay.
- 10. A filtering device according to Claim 8, characterised in that the filtering means include a second-order LC filter (F), and in that the isolation means (I) are placed on each side of the capacitor (C1) of the said filter and in that it also comprises at least two other capacitors (C') each being placed in paral·lel to the assembly formed by the isolation means and the capacitor of the filter.
- 11. A filtering device according to any one of the preceding claims, characterised in that the filtering means include a second-order LC filter (Fe) of high impedance, placed at the input of the device on the private installation side and a second filter (Fc) coupled to the first, whose activation depends directly on the isolation means (I).

- 12. A filtering device according to Claim 11, characterised in that the second filter includes a capacitor (C1) in parallel to the capacitor (C2) of the LC filter placed in the isolation means or after the said means.
- and 11, characterised in that the isolation means (I) are placed after the capacitor (C2) of the LC filter, and in that the capacitor of the second filter (C1) is placed in the isolation device (I) and in that the other two capacitors (C') are each placed in parallel to the assembly formed by the isolation means and the capacitor (C1) of the second filter.
- A private installation comprising at least one narrow-band terminal and at least one broad-band an access network carrying terminal, connected to narrow-band services and broad-band services, characterised in that it. includes at. least filtering device according to one of the preceding claims.
- 15. A private installation according to Claim 14, characterised in that the device is placed at the input of the narrow-band terminal on the network access or on the lead connecting the terminal to the network.
- 16. A private installation according to Claim 14, characterised in that the device is placed in the narrow-band terminal.
